

**CBSE Test Paper 05**  
**Chapter 2 Polynomials**

---

1. If one zero of the polynomial  $p(x) = (a^2 + 9)x^2 + 45x + 6a$  is reciprocal of the other, then the value of 'a' is **(1)**
  - a. 2
  - b. 3
  - c. 0
  - d. 1
2. If  $x - 2$  is a factor of the polynomial  $3x^3 - 7x^2 + kx - 16$ , then the value of 'k' is **(1)**
  - a. -10
  - b. 10
  - c. -2
  - d. 2
3. The zeroes of a polynomial  $x^2 - 7x + 12$  are **(1)**
  - a. both positive
  - b. both negative
  - c. both equal
  - d. one positive and one negative
4. Given that one of the zeroes of the cubic polynomial  $ax^3 + bx^2 + cx + d$  is zero, then the product of the other two zeroes is **(1)**
  - a.  $\frac{-c}{a}$
  - b.  $\frac{b}{a}$
  - c.  $\frac{-b}{a}$
  - d.  $\frac{c}{a}$
5. If ' $\alpha$ ' and ' $\beta$ ' are the zeroes of the polynomial  $3x^2 + 11x - 4$ , then the value of  $\alpha^2 + \beta^2$  is **(1)**
  - a.  $\frac{150}{9}$
  - b.  $\frac{145}{9}$
  - c.  $\frac{152}{9}$
  - d.  $\frac{144}{9}$

6. If  $\alpha, \beta$  are zeroes of  $x^2 + 5x + 5$ , find the value of  $\alpha^{-1} + \beta^{-1}$ . **(1)**
7. If -4 is a zero of the polynomial  $x^2 - x - (2k + 2)$  then find the value of k. **(1)**
8. Find a cubic polynomial with the sum, sum of the product of its zeros taken two at a time, and product of its zeroes as 3, -1 and -3 respectively. **(1)**
9. If  $p(x) = ax^2 + bx + c$ . If  $a + c = b$ , then find one of its zeroes. **(1)**
10. If  $\alpha$  and  $\beta$  are the roots of equation  $ax^2 - bx + c = 0$ , then find the value of  $\alpha + \beta$ . **(1)**
11. If the polynomial  $6x^4 + 8x^3 + 17x^2 + 21x + 7$  is divided by another polynomial  $3x^2 + 4x + 1$ , then what will be the quotient and remainder? **(2)**
12. Find the zeroes of  $4x^2 + 24x + 36$  and verify the relationship between the zeroes and their coefficients. **(2)**
13. Divide the polynomial  $p(x) = x^2 - 5x + 16$  by the polynomial  $g(x) = x - 2$  and find the quotient and the remainder. **(2)**
14. On dividing  $x^3 + 4x^2 + 3x + 2$  by  $g(x)$ , quotient and remainder were  $(x^2 - 2)$  and  $(5x + 10)$  respectively. Find  $g(x)$ . **(3)**
15. Find a cubic polynomial whose zeros are 3, 5 and -2. **(3)**
16. Find the quadratic polynomial whose zeroes are 2 and -6 respectively. Verify the relation between the coefficients and zeroes of the polynomial. **(3)**
17. Obtain all the zeroes of  $2x^4 - 7x^3 - 13x^2 + 63x - 45$  if two of its zeroes are 1 and 3. **(3)**
18. If  $\alpha$  and  $\beta$  are the zeroes of the polynomial  $x^2 + 4x + 3$ , find the polynomial whose zeroes are  $1 + \frac{\beta}{\alpha}$  and  $1 + \frac{\alpha}{\beta}$ . **(4)**
19. Polynomial  $x^4 + 7x^3 + 7x^2 + px + q$  is exactly divisible by  $x^2 + 7x + 12$ , then find the value of p and q. **(4)**
20. If two zeroes of a polynomial  $x^3 + 5x^2 + 7x + 3$  are -1 and -3, then find the third zero. **(4)**

**CBSE Test Paper 05**  
**Chapter 2 Polynomials**

**Solution**

1. b. 3

**Explanation:** Let one zero be  $\beta$  then the other zero will be  $\frac{1}{\alpha}$

$$\text{Since } \alpha\beta = \frac{c}{a} \Rightarrow \alpha \times \frac{1}{\alpha} = \frac{6a}{a^2+9}$$

$$\Rightarrow 1 = \frac{6a}{a^2+9}$$

$$\Rightarrow 6a = a^2 + 9$$

$$\Rightarrow a^2 - 6a + 9 = 0$$

$$\Rightarrow (a - 3)(a - 3) = 0 \quad a - 3 = 0 \text{ and } a - 3 = 0$$

$$\Rightarrow a = 3 \text{ and } a = 3$$

2. b. 10

**Explanation:** If the polynomial  $3x^3 - 7x^2 + kx - 16$  is exactly divisible by  $x - 2$ , then

$$p(2) = 0$$

$$\Rightarrow 3(2)^3 - 7(2)^2 + k \times 2 - 16 = 0$$

$$\Rightarrow 24 - 28 + 2k - 16 = 0$$

$$\Rightarrow -20 + 2k = 0$$

$$\Rightarrow k = 10$$

3. a. both positive

**Explanation:**  $x^2 - 7x + 12$

$$= x^2 - 4x - 3x + 12 = 0$$

$$= x(x - 4) - 3(x - 4) = 0$$

$$= (x - 4)(x - 3) = 0$$

$$\therefore x - 4 = 0 \text{ or } x - 3 = 0$$

$$\Rightarrow x = 4 \text{ or } x = 3$$

4. d.  $\frac{c}{a}$

**Explanation:** Let  $\alpha, \beta, \gamma$  are the zeroes of the given polynomial. Given :  $\alpha = 0$

To find:  $\beta\gamma$  Since,  $\alpha\beta + \beta\gamma + \gamma\alpha = \frac{c}{a}$

$$\therefore 0 \times \beta + \beta\gamma + \gamma \times 0 = \frac{c}{a} \Rightarrow \beta\gamma = \frac{c}{a}$$

5. b.  $\frac{145}{9}$

**Explanation:** Here  $a = 3, b = 11, c = -4$

$$\text{Since } \alpha^2 + \beta^2 = (\alpha + \beta)^2 - 2\alpha\beta$$

$$= \left(\frac{-b}{a}\right)^2 - 2 \times \frac{c}{a} = \frac{b^2}{a^2} - \frac{2c}{a} = \frac{b^2 - 2ac}{a^2}$$

$$\text{Putting the values of } a, b \text{ and } c, \text{ we get} = \frac{(11)^2 - 2 \times 3 \times (-4)}{(3)^2}$$

$$= \frac{121 + 24}{9}$$

$$= \frac{145}{9}$$

6. We know that sum of roots  $= \alpha + \beta = -\frac{b}{a}$

$$\Rightarrow \alpha + \beta = -5$$

$$\text{and product of roots} = \alpha\beta = \frac{c}{a} \Rightarrow \alpha\beta =$$

$$5 \quad \text{Now the given expression is :}$$

$$\alpha^{-1} + \beta^{-1} = \frac{1}{\alpha} + \frac{1}{\beta} = \frac{\alpha + \beta}{\alpha\beta} = \frac{-5}{5} = -1$$

7. Given that, -4 is a zero of the polynomial  $f(x) = x^2 - x - (2k + 2)$ , so, we have

$$f(-4) = 0$$

$$\Rightarrow (-4)^2 - (-4) - 2k - 2 = 0$$

$$\Rightarrow 16 + 4 - 2k - 2 = 0$$

$$\Rightarrow 18 - 2k = 0$$

$$\Rightarrow 2k = 18$$

$$\Rightarrow k = 9.$$

8. Any cubic polynomial is of the form  $ax^3 + bx^2 + cx + d$

$$= x^3 - (\text{sum of the zeroes}) x^2 + (\text{sum of the products of its zeroes taken two at a time}) x - (\text{product of the zeroes})$$

$$= x^3 - 3x^2 + (-1)x + (-3)$$

$$= x^3 - 3x^2 - x - 3$$

$$\text{Hence, required cubic polynomial is } x^3 - 3x^2 - x - 3$$

9. We have function  $p(x) = ax^2 + bx + c$  and  $a + c = b$   
using remainder theorem by putting  $x = -1$  we get

$$p(-1) = a(-1)^2 + b(-1) + c$$

$$= a - b + c = a + c - b$$

$$= b - b = 0$$

∴ One zero is -1.

10. Sum of the roots =  $-\frac{\text{Coefficient of } x}{\text{Coefficient of } x^2}$   
 or,  $\alpha + \beta = -\left(\frac{-b}{a}\right) = \frac{b}{a}$

11. On long division of  $6x^4 + 8x^3 + 17x^2 + 21x + 7$  by  $3x^2 + 4x + 1$  we get

$$\begin{array}{r} 2x^2 + 5 \\ 3x^2 + 4x + 1 \overline{) 6x^4 + 8x^3 + 17x^2 + 21x + 7} \\ \underline{6x^4 + 8x^3 + 2x^2} \phantom{+ 7} \\ 15x^2 + 21x + 7 \\ \underline{15x^2 + 20x + 5} \\ x + 2 \end{array}$$

Quotient =  $2x^2 + 5$ , remainder =  $x + 2$

12.  $p(x) = 4x^2 + 24x + 36$

For zeroes,  $p(x) = 0$

$$\Rightarrow 4x^2 + 24x + 36 = 0$$

$$\Rightarrow 4(x^2 + 6x + 9) = 0$$

$$\Rightarrow (x^2 + 3x + 3x + 9) = 0$$

$$\Rightarrow (x + 3)(x + 3) = 0$$

$$\Rightarrow x + 3 = 0 \text{ or } x + 3 = 0$$

$$\Rightarrow x = -3, x = -3$$

∴ Zeroes are -3, -3.

After comparing  $4x^2 + 24x + 36$  with  $ax^2 + bx + c$ , we get

Now,  $a = 4$ ,  $b = 24$ ,  $c = 36$

$$\frac{-b}{a} = \frac{-24}{4} = -6 \dots\dots(i)$$

$$\text{Sum of zeroes} = -3 + (-3) = -6 \dots\dots(ii)$$

From (i) and (ii)

$$\text{Sum of zeroes} = -\frac{b}{a}$$

$$\text{Also, } \frac{c}{a} = \frac{36}{4} = 9 \dots\dots(iii)$$

and, Product of zeroes =  $(-3) \times (-3) = 9$  ..... (iv)

From (iii) and (iv)

Product of zeroes =  $\frac{c}{a}$

13. 
$$\begin{array}{r} x-3 \\ x-2 \overline{) x^2-5x+16} \\ \underline{x^2-2x} \phantom{+16} \\ -3x+16 \\ \underline{-3x+6} \phantom{+16} \\ +10 \end{array}$$

$\Rightarrow$  Quotient =  $x - 3$ , Remainder = 10

14. Using, Dividend = Divisor  $\times$  Quotient + Remainder

$x^3 + 4x^2 + 3x + 2 = g(x) \times (x^2 - 2) + (5x + 10)$

$\Rightarrow (x^3 + 4x^2 + 3x + 2) - (5x + 10) = (x^2 - 2) \times g(x)$

$\Rightarrow x^3 + 4x^2 + 3x + 2 - 5x - 10 = (x^2 - 2) \times g(x)$

$\Rightarrow x^3 + 4x^2 - 2x - 8 = (x^2 - 2) \times g(x)$  .....(i)

$\Rightarrow (x^2 - 2)$  is a factor of  $x^3 + 4x^2 - 2x - 8$

$$\begin{array}{r} x+4 \\ x^2-2 \overline{) x^3+4x^2-2x-8} \\ \underline{-x^3} \phantom{+4x^2} \phantom{-2x} \phantom{-8} \\ 4x^2 \phantom{-2x} \phantom{-8} \\ \underline{4x^2} \phantom{-2x} \phantom{-8} \\ -2x \phantom{-8} \\ \underline{-2x} \phantom{-8} \\ 0 \end{array}$$

$\Rightarrow x^3 + 4x^2 - 2x - 8 = (x^2 - 2) (x + 4)$

$\therefore g(x) = (x + 4)$  [On comparing with (i)]

15. Let  $\alpha, \beta$  and  $\gamma$  be the zeroes of the given polynomial.

Then, we have  $\alpha = 3, \beta = 5$  and  $\gamma = -2$

Hence

$\alpha + \beta + \gamma = 3 + 5 - 2 = 6$  .....(1)

$\alpha\beta + \beta\gamma + \gamma\alpha = 3(5) + 5(-2) + (-2)3 = 15 - 10 - 6 = -1$  .....(2)

$\alpha\beta\gamma = 3(5)(-2) = -30$  .....(3)

Now, a cubic polynomial whose zeros are  $\alpha, \beta$  and  $\gamma$  is equal to

So, its zeroes are -3 and  $\frac{5}{2}$

Therefore, all the zeroes of the given fourth-degree polynomial are 1, 3, -3 and  $\frac{5}{2}$ .

18. Since  $\alpha$  and  $\beta$  are the zeroes of the quadratic polynomial  $x^2 + 4x + 3$

$$\text{So, } \alpha + \beta = -4$$

$$\text{and } \alpha\beta = 3$$

$$\text{Sum of zeroes of new polynomial} = 1 + \frac{\beta}{\alpha} + 1 + \frac{\alpha}{\beta}$$

$$= \frac{\alpha\beta + \beta^2 + \alpha\beta + \alpha^2}{\alpha\beta}$$

$$= \frac{\alpha^2 + \beta^2 + 2\alpha\beta}{\alpha\beta}$$

$$= \frac{(\alpha + \beta)^2}{\alpha\beta} = \frac{(-4)^2}{3} = \frac{16}{3}$$

$$\text{Product of zeroes} = \left(1 + \frac{\beta}{\alpha}\right) \left(1 + \frac{\alpha}{\beta}\right)$$

$$= \left(\frac{\alpha + \beta}{\alpha}\right) \left(\frac{\beta + \alpha}{\beta}\right)$$

$$= \frac{(\alpha + \beta)^2}{\alpha\beta}$$

$$= \frac{(-4)^2}{3} = \frac{16}{3}$$

So required polynomial =  $x^2 - (\text{Sum of the zeroes})x + \text{Product of the zeroes}$

$$= x^2 - \left(\frac{16}{3}\right)x + \frac{16}{3}$$

$$= \left(x^2 - \frac{16}{3}x + \frac{16}{3}\right)$$

$$= \frac{1}{3}(3x^2 - 16x + 16)$$

19. Factors of  $x^2 + 7x + 12$  :

$$x^2 + 7x + 12 = 0$$

$$\Rightarrow x^2 + 4x + 3x + 12 = 0$$

$$\Rightarrow x(x + 4) + 3(x + 4) = 0$$

$$\Rightarrow (x + 4)(x + 3) = 0$$

$$\Rightarrow x = -4, -3 \dots \text{(i)}$$

$$\text{Since } p(x) = x^4 + 7x^3 + 7x^2 + px + q$$

If  $p(x)$  is exactly divisible by  $x^2 + 7x + 12$ , then  $x = -4$  and  $x = -3$  are its zeroes. So putting  $x = -4$  and  $x = -3$ .

$$p(-4) = (-4)^4 + 7(-4)^3 + 7(-4)^2 + p(-4) + q$$

but  $p(-4) = 0$

$\therefore 0 = 256 - 448 + 112 - 4p + q$

$0 = -4p + q - 80$

$\Rightarrow 4p - q = -80 \dots(i)$

and  $p(-3) = (-3)^4 + 7(-3)^3 + 7(-3)^2 + p(-3) + q$

but  $p(-3) = 0$

$\Rightarrow 0 = 81 - 189 + 63 - 3p + q$

$\Rightarrow 0 = -3p + q - 45$

$\Rightarrow 3p - q = -45 \dots(ii)$

$4p - q = -80$

$3p - q = -45$

$$\begin{array}{r} - \quad + \quad + \\ \hline p = -35 \end{array}$$

On putting the value of  $p$  in eq. (i), we get,

$4(-35) - q = -80$

$\Rightarrow -140 - q = -80$

$\Rightarrow -q = 140 - 80$

$\Rightarrow -q = 60$

$\therefore q = -60$

Hence,  $p = -35, q = -60$

20.  $x = -1$  and  $x = -3$  are zeroes.

$\Rightarrow (x + 1)(x + 3) = x^2 + 4x + 3$

$$\begin{array}{r} x^2 + 4x + 3 \quad | \quad x^3 + 5x^2 + 7x + 3 \quad (x + 1) \\ \underline{x^3 + 4x^2 + 3x} \phantom{+ 3} \\ \phantom{x^3} x^2 + 4x + 3 \\ \underline{\phantom{x^3} x^2 + 4x + 3} \\ \phantom{x^3} \phantom{x^2} 0 \end{array}$$

Since remainder = 0, therefore  $(x + 1)$  is factor of  $x^3 + 5x^2 + 7x + 3$ .

So, required zero is given by putting  $x + 1 = 0$

$\Rightarrow x = -1$

$\therefore$  The third zero is  $-1$ .
